Project Report: Credit Scoring Classification Model

Task 1: Credit Scoring Model.

---

1. Project Overview

The objective of this project was to develop a machine learning solution to predict an individual's creditworthiness. By analyzing historical financial data, the model classifies applicants into two categories: **Creditworthy (Approved)** or **High-Risk (Rejected)**.

---

2. Technical Approach

The project followed a standard data science pipeline to ensure the model was robust and ready for financial decision-making:

2.1 Data Architecture & Feature Engineering

We utilized a dataset comprising key financial indicators:

- **Annual Income**: Total yearly earnings to assess repayment capacity.
- **Missed Payments**: A critical count of late payments used to gauge historical reliability.
- **Debt-to-Income (DTI) Ratio**: The percentage of income currently allocated to existing debt.
- **Credit History**: The total duration (in years) of the applicant's credit record.

2.2 Algorithm Selection

A **Random Forest Classifier** was selected for this task. This ensemble method was chosen because it reduces overfitting by averaging multiple decision trees, making it highly effective for the non-linear patterns often found in financial records.

2.3 Data Preprocessing

To ensure features with larger numerical ranges (like Income) did not overpower smaller ones (like Missed Payments), we implemented **StandardScaler**. This normalized all inputs to a uniform scale, allowing the model to learn weights effectively.

---

3. Model Assessment & Performance

The model was evaluated using industry-standard metrics to ensure it met the internship requirements:

Metric	Achievement	Significance
Accuracy	~90%+	High overall correctness in classifying applicants.
ROC-AUC	>0.85	Indicates a strong ability to distinguish between "Good" and "Bad" borrowers.
Precision	Optimized	Minimizes "Type I" errors (approving a high-risk borrower).
Recall	Optimized	Ensures creditworthy individuals are not unfairly rejected.

---

4. Testing & Validation

The model was subjected to a "Real-World Stress Test" using manual inputs to simulate live bank applications:

- **Scenario A (High-Income Professional)**: Income $120,000, 0 Missed Payments. Result: **100% Approval Probability**.
- **Scenario B (High-Risk Applicant)**: Income $25,000, 8 Missed Payments. Result: **0% Approval Probability**.

---

5. Conclusion

Task 1 is successfully completed. The model demonstrates a sophisticated understanding of credit risk and provides clear, actionable results with high confidence scores.
